ABSTRACT: The main challenge faced by Higgsless models of electroweak symmetry breaking is to reconcile the experimental constraints imposed by the precision electroweak data and the top quark phenomenology with the unitarity constraints imposed by longitudinal gauge boson scattering amplitudes. In this paper we expand on previous work, giving details of how delocalized fermions can be used to adjust the S parameter to zero, while keeping the T and U parameters naturally suppressed. We also show that it is possible to obtain the top quark mass, without affecting the delay of unitarity violation of the $W^+W^- \rightarrow W^+W^-$ scattering amplitude, by separating the mass scales of the fermion sector ($1/R_f$) from that of the gauge sector ($1/R_g$). The fermion sector scale $1/R_f$ is only weakly constrained by unitarity of the $t\bar{t} \rightarrow W^+W^-$ scattering amplitude; thus the ratio R_g/R_f can be quite large, and the top mass can be easily achieved. Anomalous right-handed couplings involving the third generation quarks also avoid constraints from experimental data if $1/R_f$ is sufficiently large.

1. Introduction

The only piece of the Standard Model (SM) that is still missing is the Higgs boson. In the SM its existence is required to break the Electroweak symmetry and to give mass to the W and Z bosons, as well as to the matter particles. It also provides interactions that restore unitarity to massive vector boson scattering at high energies [1]. However, it is quite possible that these effects arise through other dynamics, with different signatures than a neutral scalar boson. We must be prepared for any alternatives that nature may have chosen.

Historically, most scenarios of electroweak symmetry breaking that do not involve a Higgs boson occur through strong dynamics. The prototypical example of this is Technicolor [2, 3]. More recently, new avenues of Higgsless electroweak symmetry breaking have been realized, with inspiration coming from extra-dimensions [4]–[17]. In fact, it has been argued that these new Higgsless theories in certain limits may be dual to Technicolor [18]–[21]. Like Technicolor, the Higgsless models of electroweak symmetry breaking solve the unitarity problem by the exchange of new massive vector bosons, although the new states are typically more weakly coupled than the Techni-rhos. In any event, Higgsless theories open up new possibilities for physics beyond the standard model, which might be revealed at the Large Hadron Collider. More generally, they offer a new framework in

which to investigate those theories where the unitarity problem is addressed by vector-boson exchange.

Higgsless theories have been proposed in five warped dimensions [4]–[14], in five flat dimensions with brane kinetic terms [15], in six dimensions [16], and in four-dimensional theory space [17]. Although differing in details, all of these models have certain generic features and phenomenology [22]. The $SU(2) \times U(1)$ electroweak gauge symmetry (with possible multiple copies of the $SU(2)$'s or $U(1)$'s) is broken explicitly at certain places in the extra (real or theory-space) dimension, leaving a massless photon and a W and Z as the light vector boson states. In addition there is a tower of heavy vector bosons. It is the new contribution from these heavy states that delays the onset of unitarity violation.

The major obstacle that Higgsless theories have faced so far has been in dealing with constraints from precision electroweak measurements. Typically, the mixing between the W and Z bosons and the tower of heavy vector bosons produces effects which can be interpreted as a tree-level contribution to the electroweak S parameter. Whereas the T parameter can be made naturally small in these models, the S parameter can only be made small either by making T larger [23, 24] or by increasing the scale of the heavy vector boson tower [25]. Neither of these solutions is acceptable; in particular, a mass scale for the heavy vector bosons that is sufficient to satisfy the constraints from the S parameter is too large to solve the original unitarity problem.

Recently, a new idea has been introduced to address the issues of the S parameter. By allowing the left-handed fermion fields to have some finite extent in the extra dimensions, it is possible to cancel the vector boson contributions and to satisfy the electroweak constraints [26]–[31]. Although this appears to require fine tuning, it is conceivable that a mechanism may be found to make this natural. In any event, it is useful to see how far this scenario can be carried in order to produce a consistent alternative theory of the electroweak symmetry breaking sector.

In this paper we extend upon our previous work [27] by looking at the effects of delocalized fermions in more detail. In particular, we concentrate on the problem of incorporating a heavy top quark into this scenario. For simplicity we continue to explore these models in the context of the continuum theory-space model of Ref. [27], but we emphasize that the qualitative features that we find should arise in any Higgsless theory with delocalized fermions.

In Section 2 we briefly introduce the gauge sector of this theory. We also describe, for comparison purposes, a model (I) of the fermion sector with the fermions localized in the extra dimension. In Section 3 we give the details of our new model (II) of the fermion sector, where the fermions have some leakage into the extra dimension. We analyze the solutions of the mass equations, and show that masses of all the light fermions are easily obtained, except for the top quark. We also show that by introducing some simple assumptions in the fermion sector we can suppress flavor-changing neutral currents, leading to the standard Cabbibo-Kobayashi-Maskawa (CKM) mixing pattern.

In Section 4 we show that in Model II with delocalized fermions, it is possible to have the S , T and U parameters agree with data. We then return to the question of the top quark mass in Section 5 and show that it can also be obtained by introducing an explicit

breaking of the five-dimensional Lorentz symmetry in the fermion kinetic terms. Since this symmetry is already explicitly broken by the compactification, as well as in the brane terms, there are no theoretical barriers to this. By allowing an additional scale factor for the fifth-dimensional kinetic term for the fermions, we are able to separate the scale of the fermion masses from that of the vector boson masses. This allows us to obtain a realistic mass for the top quark, while simultaneously suppressing any dangerous right-handed couplings. However, just as in the vector boson sector, the scale of heavy fermions cannot be too large without running into unitarity problems. We address this question in Section 6, where we consider the scattering of polarized top quarks into longitudinal vector bosons ($t_L \bar{t}_L \rightarrow W_L^+ W_L^-$, where L refers to the helicity $\lambda = -$ for the fermions and L means longitudinal for the W 's). In the standard model this amplitude is unitarized by Higgs boson exchange. We show that in our model, it is unitarized by the tower of b' quarks. By requiring that the $J = 0$ partial wave amplitude remain less than $1/2$ up to some energy scale, we obtain a constraint on the mass scale of the b' states. We then investigate this constraint in conjunction with the constraint on the scale of the W' states coming from unitarity of vector boson scattering.

Finally, in Section 7, we will offer our conclusions.

2. Higgsless Theory with Fermions

2.1 Gauge Sector

We will use the continuum theory-space model of Refs. [17] and [27] to explore the interplay of the fermion sector in a Higgsless theory. First, we summarize the gauge sector. It is an $SU(2)$ gauge theory, defined on a fifth-dimensional line segment, $0 \leq y \leq \pi R$, where the boundary conditions break the gauge symmetry down to $U(1)$ at one end of the interval. The five dimensional action is

$$\mathcal{S} = \int_0^{\pi R} dy \int d^4x \left[-\frac{1}{4(\pi R)\hat{g}_5^2} W^{aMN} W_{MN}^a - \delta(y) \frac{1}{4g^2} W^{a\mu\nu} W_{\mu\nu}^a - \delta(\pi R - y) \frac{1}{4g'^2} W^{3\mu\nu} W_{\mu\nu}^3 \right], \quad (2.1)$$

where, in this equation, the indices M, N run over the 5 dimensions, and we impose the Dirichlet Boundary condition, $W_\mu^a = 0$, at $y = \pi R$ for $a \neq 3$. The boundary kinetic energy term at $y = 0$ is defined by interpreting the δ -function as $\delta(y - \epsilon)$ with $\epsilon \rightarrow 0^+$ and the fields having Neumann boundary conditions, $\partial W_\mu^a / \partial y = 0$, at $y = 0$. The δ -function and the field W_μ^3 at $y = \pi R$ should be interpreted similarly. Note that in the limit of small g and g' the theory looks like an $SU(2)$ gauge theory and a $U(1)$ gauge theory, living at the left and right ends of the fifth-dimensional interval, respectively. It is the bulk fields that connect the $SU(2)$ and the $U(1)$ theories, and transmit the breaking of the theories down to a single $U(1)_{EM}$.

The five-dimensional gauge fields can be expanded in a tower of four-dimensional Kaluza-Klein (KK) states:

$$\begin{aligned} W^{\pm\mu}(x, y) &= \sum_{n=0}^{\infty} f_n(y) W_n^{\pm\mu}(x) \\ W^{3\mu}(x, y) &= eA^\mu(x) + \sum_{n=0}^{\infty} g_n(y) Z_n^\mu(x) , \end{aligned} \quad (2.2)$$

where $W_n^{\pm\mu}$ has mass m_{W_n} , and Z_n^μ has mass m_{Z_n} . The lowest states of the tower, $W_0^{\pm\mu}$ and Z_0^μ , will be identified as the standard model $W^\pm$ and Z bosons, respectively. The masses satisfy the equations

$$\begin{aligned} \hat{m}_{W_n} \tan \hat{m}_{W_n} &= \lambda^2 \\ \left(\hat{m}_{Z_n} - \frac{\lambda^2 \lambda'^2}{\hat{m}_{Z_n}} \right) \tan \hat{m}_{Z_n} &= \lambda^2 + \lambda'^2 , \end{aligned} \quad (2.3)$$

where $\lambda \equiv g/\hat{g}_5$, and $\lambda' \equiv g'/\hat{g}_5$, and we have introduced the notation $\hat{m} \equiv m\pi R$ for dimensionless scaled masses. Solving for the masses perturbatively in λ^2 and λ'^2 , we obtain

$$\begin{aligned} m_W^2 \equiv m_{W_0}^2 &= \frac{\lambda^2}{(\pi R)^2} \left[1 - \frac{\lambda^2}{3} + \mathcal{O}(\lambda^4) \right] \\ m_Z^2 \equiv m_{Z_0}^2 &= \frac{\lambda^2 + \lambda'^2}{(\pi R)^2} \left[1 - \frac{\lambda^2 + \lambda'^2}{3} + \frac{\lambda^2 \lambda'^2}{\lambda^2 + \lambda'^2} + \mathcal{O}(\lambda^4) \right] , \end{aligned} \quad (2.4)$$

for the standard model gauge bosons, and

$$\begin{aligned} m_{W_n}^2 &= \left(\frac{n}{R} \right)^2 \left[1 + 2 \frac{\lambda^2}{(\pi n)^2} + \mathcal{O}(\lambda^4) \right] \\ m_{Z_n}^2 &= \left(\frac{n}{R} \right)^2 \left[1 + 2 \frac{\lambda^2 + \lambda'^2}{(\pi n)^2} + \mathcal{O}(\lambda^4) \right] , \end{aligned} \quad (2.5)$$

for the heavy gauge bosons.

Solving the equations of motion and applying the boundary conditions in the fifth dimension, gives the following gauge boson wave functions:

$$\begin{aligned} f_n(y) &= F_n \sin[m_{W_n}(\pi R - y)] \\ g_n(y) &= G_n \left[\cos(m_{Z_n} y) - \frac{\hat{m}_{Z_n}}{\lambda^2} \sin(m_{Z_n} y) \right] \end{aligned} \quad (2.6)$$

Requiring the KK states to be canonically normalized in the four-dimensional Lagrangian, and using Eqs. (2.3) to simplify, leads to the following expressions for the normalization constants:

$$\begin{aligned} F_n &= \hat{g}_5 \left[\frac{1}{2} \left(1 + \frac{\sin 2\hat{m}_{W_n}}{2\hat{m}_{W_n}} \right) \right]^{-1/2} \\ G_n &= \hat{g}_5 \left[\frac{1}{2} \left(1 - \frac{\sin 2\hat{m}_{Z_n}}{2\hat{m}_{Z_n}} \right) + \frac{1}{\lambda^2} \sin^2 \hat{m}_{Z_n} + \frac{\hat{m}_{Z_n}^2}{2\lambda^4} \left(1 + \frac{\sin 2\hat{m}_{Z_n}}{2\hat{m}_{Z_n}} \right) \right]^{-1/2} . \end{aligned} \quad (2.7)$$

Expanding perturbatively in λ^2 and λ'^2 gives

$$\begin{aligned}
F_0 &= \frac{g}{\lambda} \left[1 + \frac{\lambda^2}{6} + \mathcal{O}(\lambda^4) \right] \\
F_n &= \frac{\sqrt{2}g}{\lambda} \left[1 - \frac{\lambda^2}{2(n\pi)^2} + \mathcal{O}(\lambda^4) \right] \quad n = 1, 2, \dots \\
G_0 &= \frac{g\lambda}{\sqrt{\lambda^2 + \lambda'^2}} \left[1 - \frac{\lambda^4 + 2\lambda^2\lambda'^2 - 2\lambda'^4}{6(\lambda^2 + \lambda'^2)} + \mathcal{O}(\lambda^4) \right] \\
G_n &= \frac{\sqrt{2}g\lambda}{n\pi} \left[1 - \frac{3}{2} \frac{\lambda^2 + \lambda'^2}{(n\pi)^2} + \mathcal{O}(\lambda^4) \right] \quad n = 1, 2, \dots \quad .
\end{aligned} \tag{2.8}$$

2.2 Fermion Sector: Model I

It is useful to consider first a model with localized fermions, for comparison purposes. The continuum limit of the fermion action considered in ref. [17] can be written

$$\mathcal{S}^{(I)} = \int_0^{\pi R} dy \int d^4x \left[\delta(y) i\bar{\psi}_L \not{D} \psi_L + \delta(\pi R - y) i\bar{\psi}_R \not{D} \psi_R \right] , \tag{2.9}$$

where the covariant derivatives on the left- and right-handed fields are

$$\begin{aligned}
\not{D} \psi_L &= \left(\not{\partial} - iT^a W^a(y) - iY_L W^3(\pi R) \right) \psi_L \\
\not{D} \psi_R &= \left(\not{\partial} - iY_R W^3(y) \right) \psi_R .
\end{aligned} \tag{2.10}$$

Note that the left-handed field ψ_L lives at $y = 0$ but couples also to the gauge field W^3 at $y = \pi R$. This non-locality is perfectly natural from the standpoint of a continuum theory-space model. In the theory-space interpretation $W^a(0)$ and $W^3(\pi R)$ are just the gauge fields for independent $SU(2)$ and $U(1)$ gauge groups, and y is a (continuous) label for the independent gauge groups.

To give the fermions a mass in this model, a nonlocal mass term involving a Wilson line running between the two branes must be included. However, the most critical problem with this fermion action is that it produces electroweak radiative corrections that are too large. Therefore, we are led to a theory with delocalized fermions.

3. Fermion Sector: Model II

Drawing on the analogy of the gauge action (2.1), which has $SU(2)$ and $U(1)$ kinetic terms peaked at the two ends of the interval and connected through the bulk kinetic term, we considered in Ref. [27] a theory with left-handed and right-handed fermion kinetic terms peaked at the two ends of the interval and connected through a bulk fermion kinetic term. The fermion action is

$$\begin{aligned}
\mathcal{S}^{(II)} &= \int_0^{\pi R} dy \int d^4x \left[\frac{1}{\pi R} \left(\frac{i}{2} \bar{\psi} \Gamma^M D_M \psi + \text{h.c.} - M \bar{\psi} \psi \right) \right. \\
&\quad \left. + \delta(y) \frac{1}{t_L^2} i\bar{\psi}_L \not{D} \psi_L + \delta(\pi R - y) \left(\frac{1}{t_{u_R}^2} i\bar{u}_R \not{D} u_R + \frac{1}{t_{d_R}^2} i\bar{d}_R \not{D} d_R \right) \right] , \tag{3.1}
\end{aligned}$$

The five-dimensional Dirac matrices are defined in terms of the four-dimensional ones by $\Gamma^M = (\gamma^\mu, -i\gamma^5)$. The five-dimensional fermion is equivalent to a four-dimensional Dirac fermion, $\psi = \psi_L + \psi_R$, where ψ_L and ψ_R are $SU(2)$ doublets, $\psi_L = (u_L, d_L)$ and $\psi_R = (u_R, d_R)$. We have written the action for one doublet, consisting of an up and a down quark. We will discuss the possibility of more generations and mixing in Section 3.2. We can assume the bulk mass M to be real in Eq. (3.1) without any loss of generality. Any imaginary part of M can be removed by the replacement $\psi \rightarrow e^{(i\text{Im}M)y}\psi$. The sign of M , however, is physical. The boundary kinetic energy term at $y = 0$ is defined by interpreting the δ -function as $\delta(y - \epsilon)$ for $\epsilon \rightarrow 0^+$ with the boundary condition $\psi_R = 0$ at $y = 0$. Similarly, the boundary term at $y = \pi R$ is defined by interpreting the δ -function as $\delta(\pi R - y + \epsilon)$ with the boundary condition $\psi_L = 0$ at $y = \pi R$. The general treatment of possible fermion boundary conditions can be found in Ref. [7].

The covariant derivative in Eq. (3.1) is

$$D_M\psi = (\partial_M - iT^a W_M^a(y) - iY_L W_M^3(\pi R))\psi, \quad (3.2)$$

where Y_L is the ψ_L hypercharge. At the interval ends the four-dimensional part of the covariant derivative (3.2) becomes:

$$\begin{aligned} (\not{D}\psi_L)_{y=0} &= \left(\not{\partial} - iT^a W^a(0) - iY_L W^3(\pi R) \right) \psi_L \\ (\not{D}\psi_R)_{y=\pi R} &= \left(\not{\partial} - iT^3 W^3(\pi R) - iY_L W^3(\pi R) \right) \psi_R \\ &= \left(\not{\partial} - iY_R W^3(\pi R) \right) \psi_R, \end{aligned} \quad (3.3)$$

where the ψ_R hypercharge, Y_R , is related to Y_L by $Y_R = T^3 + Y_L$, as in the SM. Note that Y_R is a 2×2 diagonal matrix, with the u_R hypercharge on the upper left, and the d_R hypercharge on the lower right. Therefore, at $y = \pi R$ the covariant derivative term, $\bar{\psi}_R \not{D}\psi_R$, splits into two separately gauge invariant terms, $\bar{u}_R \not{D}u_R$ and $\bar{d}_R \not{D}d_R$, as in Eq. (3.1). Note also that in the limit of small t_L , t_{u_R} , and t_{d_R} the action $\mathcal{S}^{(II)}$ describes massless left-handed fermions gauged under an $SU(2) \times U(1)$ group living on the left end of the fifth-dimensional interval, and massless right-handed fermions gauged under a $U(1)$ living on the right end of the interval, exactly as in model I. It is the presence of the bulk fields which allow these light states to communicate with each other, supplying the analog of the Yukawa coupling of the SM, and giving mass to the fermions.

3.1 Fermion Masses and Wave Functions

Let χ denote either u , the up-type fermions, or d , the down-type fermions. The fermion fields can be expanded in a tower of four-dimensional KK states:

$$\begin{aligned} \chi_L(x, y) &= \sum_{n=0}^{\infty} \alpha_n(y) \chi_{n_L}(x) \\ \chi_R(x, y) &= \sum_{n=0}^{\infty} \beta_n(y) \chi_{n_R}(x). \end{aligned} \quad (3.4)$$

The four dimensional fields χ_{n_L} and χ_{n_R} are the left-handed and right-handed projection, respectively, of a mass- m_n Dirac fermion, $\chi_n = \chi_{n_L} + \chi_{n_R}$. Wave-function and mass equations are obtained by diagonalizing the free-field action. Turning off the gauge couplings, the action of Eq. (3.1) becomes $\mathcal{S}_u^{\text{free}} + \mathcal{S}_d^{\text{free}}$, where

$$\begin{aligned} \mathcal{S}_\chi^{\text{free}} = \int_0^{\pi R} dy \int d^4x \left[\frac{1}{\pi R} (i\bar{\chi}_L \not{\partial} \chi_L + i\bar{\chi}_R \not{\partial} \chi_R \right. \\ \left. - \frac{1}{2} (\bar{\chi}_R \partial_5 \chi_L - \bar{\chi}_L \partial_5 \chi_R + \text{h.c.}) - M (\bar{\chi}_R \chi_L + \bar{\chi}_L \chi_R) \right) \\ \left. + \delta(y - \epsilon) \frac{1}{t_L^2} i\bar{\chi}_L \not{\partial} \chi_L + \delta(\pi R - \epsilon - y) \frac{1}{t_{\chi_R}^2} i\bar{\chi}_R \not{\partial} \chi_R \right] . \end{aligned} \quad (3.5)$$

In Eq. (3.5) we have explicitly included a finite ϵ to push the delta-function terms slightly away from the interval ends, allowing us to unambiguously impose the boundary conditions

$$\begin{aligned} \chi_R &= 0 \text{ at } y = 0 \\ \chi_L &= 0 \text{ at } y = \pi R . \end{aligned} \quad (3.6)$$

The field equations in the bulk can be obtained by variation of $\mathcal{S}_\chi^{\text{free}}$. Integrating these equations around the delta-functions, taking the limit $\epsilon \rightarrow 0$, and using the boundary conditions (3.6), leads to alternative expressions for the boundary limits:*

$$\begin{aligned} \lim_{y \rightarrow 0^+} \chi_R &= -\frac{1}{t_L^2} i \not{\partial} \chi_L(0) \\ \lim_{y \rightarrow \pi R^-} \chi_L &= -\frac{1}{t_{\chi_R}^2} i \not{\partial} \chi_R(\pi R) . \end{aligned} \quad (3.7)$$

It is now most convenient to treat the action as finite in the bulk ($0 < y < \pi R$) with Eq. (3.7) as boundary conditions. In this case the bulk equations of motion become

$$\begin{aligned} \dot{\alpha}_n + M\alpha_n - m_n\beta_n &= 0 \\ \dot{\beta}_n - M\beta_n + m_n\alpha_n &= 0 , \end{aligned} \quad (3.8)$$

with the boundary conditions

$$\begin{aligned} \beta_n(0) &= -\frac{\hat{m}_n}{t_L^2} \alpha_n(0) \\ \alpha_n(\pi R) &= -\frac{\hat{m}_n}{t_{\chi_R}^2} \beta_n(\pi R) . \end{aligned} \quad (3.9)$$

(Recall that masses with a hat are expressed in units of $(\pi R)^{-1}$; *i.e.*, $\hat{m} \equiv m\pi R$.) The solutions to these equations are simplest in the case of zero bulk mass M . We study this case first and then look at the numerical solutions for nonzero M .

*Comparing Eq. (3.6) with Eq. (3.7), we see that χ_R has a discontinuity at $y = 0$, but χ_L is continuous. Similarly, χ_L is discontinuous at $y = \pi R$, but χ_R is continuous.

(i) $M = 0$. With no bulk mass, the solutions of Eqs. (3.8) are

$$\begin{aligned}\alpha_n &= A_n \left[\cos(m_n y) - \frac{\hat{m}_n}{t_L^2} \sin(m_n y) \right] \\ \beta_n &= -A_n \left[\frac{\hat{m}_n}{t_L^2} \cos(m_n y) + \sin(m_n y) \right] .\end{aligned}\quad (3.10)$$

Applying the boundary conditions given in Eqs. (3.9) to these solutions leads to an equation for the fermion masses,

$$(t_L^2 + t_{\chi R}^2) \hat{m}_n \tan \hat{m}_n + \hat{m}_n^2 = t_L^2 t_{\chi R}^2 . \quad (3.11)$$

The lowest mass state of the KK tower corresponds to a standard model fermion. This light mass can be easily obtained in a perturbation expansion if we assume t_L^2 to be small:

$$\hat{m}_0 = \frac{t_L t_{\chi R}}{\sqrt{1 + t_{\chi R}^2}} \left[1 - \frac{1 + t_{\chi R}^2 + t_{\chi R}^4/3}{2(1 + t_{\chi R}^2)^2} t_L^2 + \mathcal{O}(t_L^4) \right] . \quad (3.12)$$

If we also assume $t_{\chi R}^2$ to be small, the heavy state masses are

$$\hat{m}_n = \pi \left(n - \frac{1}{2} \right) \left[1 + \frac{t_L^2 + t_{\chi R}^2}{\pi^2 \left(n - \frac{1}{2} \right)^2} + \mathcal{O}(t^4) \right] ; \quad n = 1, 2, \dots . \quad (3.13)$$

The normalization factor A_n can be fixed by requiring that the KK states be canonically normalized in the four-dimensional Lagrangian. We obtain

$$A_n = \left[\frac{1}{2} \left(1 + \frac{\sin 2\hat{m}_n}{2\hat{m}_n} \right) + \frac{1}{t_L^2} \cos^2 \hat{m}_n + \frac{\hat{m}_n^2}{2t_L^4} \left(1 - \frac{\sin 2\hat{m}_n}{2\hat{m}_n} \right) \right]^{-1/2} . \quad (3.14)$$

For t_L^2 small this gives

$$A_0 = t_L \left[1 - \frac{1 + t_{\chi R}^2 + t_{\chi R}^4/3}{2(1 + t_{\chi R}^2)^2} t_L^2 + \mathcal{O}(t_L^4) \right] , \quad (3.15)$$

for the lightest state, and for both t_L^2 and $t_{\chi R}^2$ small this gives

$$A_n = \frac{\sqrt{2} t_L^2}{\pi \left(n - \frac{1}{2} \right)} \left[1 - \frac{3}{2} \frac{t_L^2 + t_{\chi R}^2}{\pi^2 \left(n - \frac{1}{2} \right)^2} + \mathcal{O}(t^4) \right] ; \quad n = 1, 2, \dots , \quad (3.16)$$

for the heavy states.

From Eq. (3.12) we see that the lightest fermion mass is suppressed by the factor $t_L t_{\chi R}$. For small values of these parameters this lightest Dirac fermion lies mainly on the branes, with small contribution from the bulk. The left-handed bulk wave function $\alpha_0(y)$ goes to zero as $t_L \rightarrow 0$, and the right-handed bulk wave function $\beta_0(y)$ goes to zero as $t_R \rightarrow 0$. Since the fermion masses arise from the ∂_5 -terms, which mix left-handed and right-handed wave functions, it follows that m_0 goes to zero, as either $t_L \rightarrow 0$ or $t_R \rightarrow 0$.

Figure 1: Masses of fermions, as a function of the bulk mass, for $t_L = 10^{-1}$, $t_R = 1$, and $1/R = 500$ GeV.

Note also that Eq. (3.12) and Eq. (3.13) are symmetric in t_L and t_{χ_R} . This was expected, since the mass equation is $t_L - t_{\chi_R}$ symmetric. However, we shall treat t_L and t_{χ_R} differently. For starters, t_L is an $SU(2)$ invariant parameter, whereas t_{χ_R} can have different values for the up and down fermions. We shall take this distinction further by assuming that t_L is universal for all quarks and leptons, and that the different particle masses are determined by t_{χ_R} . We shall find in section 4 that if t_L is of order λ , it can be used to cancel the positive contribution to the S -parameter that comes from the gauge sector. To have an idea of the orders of magnitude involved, let us assume $R^{-1} \sim 1$ TeV and $t_L \sim \lambda \sim 10^{-1}$. Then t_{χ_R} ranges from $\sim 10^{-11}$ for the lightest neutrino, to $\sim 10^{-2}$ for the charm quark. We shall return to the issue of the third generation quarks shortly.

(ii) $M \neq 0$. For nonzero bulk mass, the analysis is similar; the equations are just a bit longer. The equation for the fermion masses becomes

$$\left[(\hat{m}_n^2 + t_L^2 t_{\chi_R}^2) \hat{M} + (t_L^2 + t_{\chi_R}^2) \hat{m}_n^2 \right] T(m_n) = t_L^2 t_{\chi_R}^2 - \hat{m}_n^2, \quad (3.17)$$

where the function $T(m_n)$ depends on the relation between m_n and M :

$$T(m_n) = \begin{cases} \frac{\tan \sqrt{\hat{m}_n^2 - \hat{M}^2}}{\sqrt{\hat{m}_n^2 - \hat{M}^2}} & \text{for } m_n > |M| \\ \frac{\tanh \sqrt{\hat{M}^2 - \hat{m}_n^2}}{\sqrt{\hat{M}^2 - \hat{m}_n^2}} & \text{for } |M| > m_n . \end{cases} \quad (3.18)$$

For a large and positive bulk mass $\hat{M} > 0$, $\hat{M} \gg 1$, there is one light solution to this mass equation, given approximately by

$$\hat{m}_0^2 \approx t_L^2 t_{\chi_R}^2 e^{-2\hat{M}} . \quad (3.19)$$

For a large and negative bulk mass $\hat{M} < 0$, $|\hat{M}| \gg 1$, there are two light solutions, which are asymptotically given by (for $t_L < t_{\chi_R}$)

$$\begin{aligned} \hat{m}_0^2 &\approx 2|\hat{M}|t_L^2 \\ \hat{m}_1^2 &\approx 2|\hat{M}|t_{\chi_R}^2 . \end{aligned} \quad (3.20)$$

This behavior is displayed in Fig. 1, where we plot the mass states as a function of the bulk mass M , with the other parameters fixed at $t_L = 10^{-1}$, $t_{\chi_R} = 1$, and $1/R = 500$ GeV. The transformation $M \rightarrow -M$ can be shown to be equivalent to a reflection in the fifth dimension. Since the boundary conditions (3.6) that we have imposed are asymmetric in this reflection, we obtain the asymmetric behavior in $M \rightarrow -M$ of Fig. 1, even in the absence of the brane kinetic terms. The heavier modes are less asymmetric, because they are less affected by the boundaries.

3.2 Multiple Generations and Fermion Mixing

It is not difficult to implement multiple generations in our fermion model II. In general the bulk mass, M , and the normalizations of the brane kinetic terms, t_L^{-2} , $t_{u_R}^{-2}$, and $t_{d_R}^{-2}$, would be independent 3×3 matrices for both the leptons and the quarks. However, this proliferation of mixing matrices would open the door to large flavor-changing neutral currents, which must somehow be avoided. The simplest way to achieve this is to restrict all of the flavor physics to the right brane, and impose a global $U(3)_{\text{quark}} \times U(3)_{\text{lepton}}$ symmetry on the quark and lepton doublets in the bulk and on the left brane. This flavor symmetry would only be broken by the kinetic terms on the right brane (which, incidentally, is also the only place where the $SU(2)$ weak gauge symmetry is broken). The generalization of the fermion action in Eq. (3.1) is

$$\begin{aligned} S^{(II)} = \int_0^{\pi R} dy \int d^4x \left[\frac{1}{\pi R} \left(\frac{i}{2} \bar{\psi}^i \Gamma^M D_M \psi^i + \text{h.c.} - M \bar{\psi}^i \psi^i \right) \right. \\ \left. + \delta(y) \frac{1}{t_L^2} i \bar{\psi}_L^i \not{D} \psi_L^i + \delta(\pi R - y) \left(i \bar{u}_R^i K_u^{ij} \not{D} u_R^j + i \bar{d}_R^i K_d^{ij} \not{D} d_R^j \right) \right] , \end{aligned} \quad (3.21)$$

where i and j are generation indices, and there is an equivalent contribution for leptons. In principle the t_L and M parameters, as well as the K matrices, can be different for

the lepton and quark sectors. The five-dimensional fermion fields ψ^i 's can be considered four-dimensional Dirac fermions, which are also $SU(2)$ doublets:

$$\psi^i = \psi_L^i + \psi_R^i = \begin{pmatrix} u_L^i \\ d_L^i \end{pmatrix} + \begin{pmatrix} u_R^i \\ d_R^i \end{pmatrix} \quad (3.22)$$

The quark sector matrices K_u and K_d are arbitrary Hermitian matrices; however, we can exploit the $U(3)_{\text{quark}}$ symmetry of the quark fields in the bulk and on the left brane to reduce the number of real physical parameters to $9 + 9 - (9 - 1) = 10$, where we have taken into account the fact that the $U(1)$ part of $U(3)$ is just an overall phase symmetry. We can identify these 10 parameters as the six quark masses, and the four physical parameters of the CKM matrix. To see how this works, we first perform an $SU(3)$ transformation on the ψ^i to diagonalize K_u . Thus, without loss of generality, we can assume $K_u^{ij} = (t_{u_{iR}}^{-2})\delta^{ij}$. We can also assume that K_d^{ij} is diagonalized by a unitary matrix V , so that $K_d^{ij} = V^{ik}(t_{d_{kR}}^{-2})(V^\dagger)^{kj}$. We now relate the (primed) gauge eigenstates to the (unprimed) mass eigenstates by the redefinition $d_{L,R}^{\prime j} = V^{ij}d_{L,R}^j$. The action now becomes

$$\begin{aligned} \mathcal{S}^{(II)} = \int_0^{\pi R} dy \int d^4x \left[\frac{1}{\pi R} \left(\frac{i}{2} \bar{\psi}^i \Gamma^M D_M \psi^i + \text{h.c.} - M \bar{\psi}^i \psi^i \right) \right. \\ \left. + \delta(y) \frac{1}{t_L^2} i \bar{\psi}_L^i \not{D} \psi_L^i + \delta(\pi R - y) \left(\frac{1}{t_{u_{iR}}^2} i \bar{u}_R^i \not{D} u_R^i + \frac{1}{t_{d_{iR}}^2} i \bar{d}_R^i \not{D} d_R^i \right) \right], \quad (3.23) \end{aligned}$$

where

$$\psi_L^i = \begin{pmatrix} u_L^i \\ V^{ij} d_L^j \end{pmatrix}, \quad \psi_R^i = \begin{pmatrix} u_R^i \\ V^{ij} d_R^j \end{pmatrix}. \quad (3.24)$$

The unitary matrix V corresponds precisely to the CKM matrix in the SM, only arising in terms that involve the exchange of charged $SU(2)$ gauge bosons. Just as for the CKM matrix, it can be reduced to three real parameters and one phase, via five independent phase redefinitions of the $u_{L,R}$ and $d_{L,R}$ fields.

It is not difficult to see that any implementations of the SM can be mapped into this picture. In the lepton sector, for example, we could induce a see-saw mechanism by including a Majorana mass term for the neutrino, at $y = \pi R$: in that case the matrix V would contain two more physical parameters, corresponding to the Majorana phases of the MNS matrix. Alternatively, we could have a zero-mass neutrino, by imposing the boundary condition $\nu_R = 0$ at $y = \pi R$. In that case the number of physical parameters would be $9 - (9 - 3) = 3$, corresponding to the three lepton masses.

4. Electroweak Constraints

In Ref. [17] we showed that the electroweak constraints in model I could be parametrized to order λ^2 in terms of the oblique parameters S , T , and U [36]. In Ref. [27] we found that this result also applies to model II if we assume that $t_L \sim \lambda$ and we neglect the contribution of t_{χ_R} . In this section we shall review these results, filling in some of the details for both

models. We also extend these results by investigating the effects of a small but nonzero $t_{\chi R}$.

We begin by discussing the couplings of the light fermions to the tower of vector bosons. The simplest coupling to obtain is just that of the massless photon. Normalizing the four-dimensional photon field, we obtain a relation for the electromagnetic coupling that is valid in all of the fermion models considered in this paper:

$$e^2 = \left(\frac{1}{\hat{g}_5^2} + \frac{1}{g^2} + \frac{1}{g'^2} \right)^{-1} . \quad (4.1)$$

This relation holds, independent of how the fermions are incorporated in the model, due to the fact that the photon wave function is flat.

The couplings of the light fermions to the charged and neutral vector bosons can be expressed in terms of the following interaction Lagrangians

$$\begin{aligned} \mathcal{L}_{CC} &= \frac{W_n^{+\mu}}{\sqrt{2}} \bar{u} [g_{Ln}^{CC} \gamma_\mu P_L + g_{Rn}^{CC} \gamma_\mu P_R] d + \text{h.c.} \\ \mathcal{L}_{NC} &= Z_n^\mu \bar{\psi} [g_{Ln}^{NC} T^3 \gamma_\mu P_L + g_{Rn}^{NC} T^3 \gamma_\mu P_R + g_{Qn}^{NC} Q \gamma_\mu] \psi + \text{h.c.} \end{aligned} \quad (4.2)$$

Let us investigate these couplings for both models.

(i) Couplings in Model I. In model I with brane-localized fermions the couplings are determined by the values of the light boson wavefunctions at the boundaries. The right-handed couplings are both zero,

$$g_{Rn}^{CC(I)} = g_{Rn}^{NC(I)} = 0 , \quad (4.3)$$

while the remaining couplings are given by

$$\begin{aligned} g_{Ln}^{CC(I)} &= f_n(0) \\ g_{Ln}^{NC(I)} &= g_n(0) - g_n(\pi R) \\ g_{Qn}^{NC(I)} &= g_n(\pi R) . \end{aligned} \quad (4.4)$$

It is not difficult to show that the couplings of the fermions to all of the heavier vector boson states in model I are suppressed by a factor of $m_W/m_{W_n} \approx \lambda/(n\pi)$, relative to their couplings to the standard model W and Z . We find for $n \geq 1$

$$\begin{aligned} g_{Ln}^{CC(I)} &= g \left(\frac{\sqrt{2}m_W}{m_{W_n}} \right) [1 + \mathcal{O}(\lambda^2)] \\ g_{Ln}^{NC(I)} &= g \left(\frac{\sqrt{2}m_W}{m_{W_n}} \right) \frac{g^2 + (-1)^n g'^2}{g^2} [1 + \mathcal{O}(\lambda^2)] \\ g_{Qn}^{NC(I)} &= -g \left(\frac{\sqrt{2}m_W}{m_{W_n}} \right) (-1)^n \frac{g'^2}{g^2} [1 + \mathcal{O}(\lambda^2)] . \end{aligned} \quad (4.5)$$

This implies that the contribution of the heavier vector bosons to four-fermion operators at zero-momentum transfer are suppressed by a factor of λ^4 relative to the standard model W

and Z contributions. (There is a relative factor of λ^2 from the couplings and an additional factor of λ^2 due to the heavy vector boson masses in the boson propagator.) Therefore, to order λ^2 , we only need to consider the couplings to the standard model W and Z for electroweak precision measurements.

We have now seen in model I that only the couplings g_{L0}^{CC} , g_{L0}^{NC} , and g_{Q0}^{NC} are relevant to electroweak precision measurements at order λ^2 . Therefore, the deviations from the standard model can be parametrized in terms the oblique parameters S , T , and U [36]. Any additional universal parameters, such as those considered in Ref. [37] can be neglected at this order. Following Ref. [38], the S , T , and U parameters appear as deviations in relations of the universal couplings of the fermions to the W and Z gauge bosons. Taking α , m_W , and m_Z as the fundamental input observables, we find

$$\begin{aligned} g_{L0}^{CC} &= \frac{e}{s} \left[1 + \frac{\alpha S}{4s^2} - \frac{c^2 \alpha T}{2s^2} - \frac{(c^2 - s^2) \alpha U}{8s^4} \right] \\ g_{L0}^{NC} &= \frac{e}{sc} \left[1 + \frac{\alpha S}{4s^2} - \frac{(c^2 - s^2) \alpha T}{2s^2} - \frac{(c^2 - s^2) \alpha U}{8s^4} \right] \\ g_{Q0}^{NC} &= -\frac{es}{c} \left[1 + \frac{\alpha T}{2s^2} + \frac{\alpha U}{8s^4} \right] , \end{aligned} \quad (4.6)$$

where $c \equiv m_W/m_Z$ and $s \equiv (1 - c^2)^{1/2}$. The choice of α , m_W , and m_Z as inputs is convenient for our purposes, since their relation to the parameters in the Lagrangian is independent of how the fermions are incorporated into the theory. Thus, s and c , and therefore equations (4.6) are independent of which model of fermions we are using. Note that our choice of definition for $\sin^2 \theta_W$ is different from that used in Ref. [38].

In the fermion model I, we obtain

$$\begin{aligned} g_{L0}^{CC(I)} &= \frac{e}{s} [1 + \lambda^2/6 + \mathcal{O}(\lambda^4)] \\ g_{L0}^{NC(I)} &= \frac{e}{sc} [1 + \lambda^2/6 + \mathcal{O}(\lambda^4)] \\ g_{Q0}^{NC(I)} &= -\frac{es}{c} [1 + \mathcal{O}(\lambda^4)] . \end{aligned} \quad (4.7)$$

Thus, we find in this theory

$$\begin{aligned} \alpha S &= 2s^2 \lambda^2 / 3 \\ \alpha T &= 0 \\ \alpha U &= 0 . \end{aligned} \quad (4.8)$$

This nonzero S in fermion model I is problematic, because in order to make it small enough to be compatible with data, the tower of vector boson states must be too heavy to salvage the unitarity bound.

(ii) Couplings in Model II. Let us begin by assuming that $t_{\chi_R} = 0$. To the extent to which we can neglect t_{χ_R} , the right-handed couplings of the light fermions, g_{Rn}^{CC} and g_{Rn}^{NC} , are also negligible. The remaining couplings of the light fermions in Model II can be

expressed

$$\begin{aligned}
g_{Ln}^{CC(II)} &= g_{Ln}^{CC(I)} \int_0^{\pi R} dy \left[\frac{1}{\pi R} + \frac{1}{t_L^2} \delta(y) \right] \left(\frac{f_n(y)}{f_n(0)} \right) \alpha_{u_0}(y) \alpha_{d_0}(y) \\
g_{Ln}^{NC(II)} &= g_{Ln}^{NC(I)} \int_0^{\pi R} dy \left[\frac{1}{\pi R} + \frac{1}{t_L^2} \delta(y) \right] \left(\frac{g_n(y) - g_n(\pi R)}{g_n(0) - g_n(\pi R)} \right) \alpha_{\chi_0}(y)^2 \\
g_{Qn}^{NC(II)} &= g_{Qn}^{NC(I)} ,
\end{aligned} \tag{4.9}$$

For $t_{\chi R} = 0$, the left-handed fermion wavefunctions within a doublet are identical, $\alpha_u = \alpha_d$.

If we assume that $t_L \approx \lambda$, the couplings of the light fermions to the heavier vector bosons are suppressed by a factor of $m_W/m_{W_n} \approx \lambda/(\lambda\pi)$, relative to their couplings to the standard model W and Z , just as in model I. Although the bulk fermions have a larger overlap with the heavy vector bosons (of order $1/\lambda^2$), this is compensated by the small probability for the light fermions to leak into the bulk (of order t_L^2). Thus, the only effect is that the expressions (4.5) for model I are multiplied by an overall coefficient of order $t_L^2/\lambda^2 \sim 1$. As an example, for $M = 0$, the left-handed charged-current and neutral-current couplings are modified, for n odd, to

$$\begin{aligned}
g_{Ln}^{CC(II)} &= g_{Ln}^{CC(I)} \left[1 - \frac{2t_L^2}{\lambda^2} + \mathcal{O}(\lambda^2, t^2) \right] \\
g_{Ln}^{NC(II)} &= g_{Ln}^{NC(I)} \left[1 - \frac{2t_L^2}{\lambda^2} \frac{g^2}{g^2 - g'^2} + \mathcal{O}(\lambda^2, t^2) \right] .
\end{aligned} \tag{4.10}$$

The $g_{Ln}^{NC(II)}$ and $g_{Ln}^{CC(II)}$ couplings, for $n > 0$ and even, are not affected by the delocalization at leading order, and the $g_{Qn}^{NC(II)}$ coupling is not affected at any order. Thus, the argument for ignoring the contributions of the heavy vector bosons to four-fermion operators holds equally in model II, as it did in model I.

As for the couplings g_{L0}^{CC} and g_{L0}^{NC} of the light fermions to the standard model vector bosons, they are multiplied by a small suppression factor in model II, relative to the couplings in model I. This is seen from the fact that the fermion wave functions are normalized by

$$1 = \int_0^{\pi R} dy \left[\frac{1}{\pi R} + \frac{1}{t_L^2} \delta(y) \right] \alpha_\chi(y)^2 , \tag{4.11}$$

while the factors in parentheses in equations (4.9) are positive and less than one:

$$0 \leq \frac{f_0(y)}{f_0(0)} \approx \frac{g_0(y) - g_0(\pi R)}{g_0(0) - g_0(\pi R)} \approx 1 - \frac{y}{\pi R} \leq 1 . \tag{4.12}$$

The suppression factors for g_{L0}^{CC} and g_{L0}^{NC} are identical to leading order in λ^2 .

Evaluating the integrals, we obtain

$$\begin{aligned}
g_{L0}^{CC(II)} &= g_{L0}^{CC(I)} (1 - A t_L^2) \\
g_{L0}^{NC(II)} &= g_{L0}^{NC(I)} (1 - A t_L^2) \\
g_{Q0}^{NC(II)} &= g_{Q0}^{NC(I)} ,
\end{aligned} \tag{4.13}$$

where

$$A = e^{-\hat{M}} \frac{\sinh \hat{M}}{\hat{M}} - \frac{1}{2\hat{M}} \left(1 - e^{-\hat{M}} \frac{\sinh \hat{M}}{\hat{M}} \right). \quad (4.14)$$

In the limit $\hat{M} \rightarrow 0$ we find $A \rightarrow 1/2$. This was the main result of Ref. [27]. By allowing the fermions to extend into the bulk, as in model II, one can cancel the effects of S in electroweak measurements. Comparing Eq. (4.13) with Eq. (4.7), we see that S can effectively be set to zero (while retaining $T = U = 0$) by the choice

$$t_L^2 = \frac{\lambda^2}{6A}. \quad (4.15)$$

Finally, let us now consider the effects of a small, but nonzero t_{χ_R} . A small t_{χ_R} will modify the couplings g_{Ln}^{CC} , g_{Ln}^{NC} , and g_{Qn}^{NC} only slightly, since it only contributes at order t^4 at the earliest. The most important effect will be the introduction of nonzero right-handed couplings for the light fermions:

$$\begin{aligned} g_{Rn}^{CC(II)} &= \int_0^{\pi R} dy \frac{1}{\pi R} f_n(y) \beta_{u_0}(y) \beta_{d_0}(y) \\ g_{Rn}^{NC(II)} &= \int_0^{\pi R} dy \frac{1}{\pi R} (g_n(y) - g_n(\pi R)) \beta_{\chi_0}(y)^2. \end{aligned} \quad (4.16)$$

For small t_R , we note that $\beta_\chi(y) \sim \mathcal{O}(t_{\chi_R})$, so that the right-handed charged couplings will only be important for the third generation. Up to corrections of order λ^2 and t^2 , we obtain for $M = 0$ the following right-handed couplings between the light fermions and the standard model W and Z bosons:

$$\begin{aligned} g_{R0}^{CC(II)} &= \frac{g}{2} t_{u_R} t_{d_R} [1 + \mathcal{O}(\lambda^2, t^2)] \\ g_{R0}^{NC(II)} &= \frac{g}{2c} t_{\chi_R}^2 [1 + \mathcal{O}(\lambda^2, t^2)], \end{aligned} \quad (4.17)$$

where $c \equiv m_W/m_Z$.

5. The Top Quark

In Section 3.1 it was shown that the fermion masses are suppressed by the factor $t_L t_{\chi_R}$. In Section 4, we saw that we could choose t_L to cancel gauge sector contributions to the S parameter, thereby relating t_L to λ by Eq. (4.15). Thus, we are left with t_{χ_R} as the final degree of freedom to fit the fermion masses. This works well for all of the light fermions, except the top quark.

Recall that the overall mass scale is set by $1/R$, which is required to be less than about a TeV in order to sufficiently delay unitarity in $W_L^+ W_L^- \rightarrow W_L^+ W_L^-$ scattering. Then with t_L fixed to cancel the contributions to the S parameter, it is impossible to obtain a realistic top quark mass of 175 GeV. For example, for $1/R = 500$ GeV, $M = 0$, and t_L fixed by Eq. (4.15), the lightest fermion mass solution to Eq. (3.17) has a maximum value of about

Figure 2: Mass of the lightest fermion, as a function of the bulk mass, for t_L chosen to adjust the S -parameter to zero, and $1/R = 500$ GeV. The curves correspond to several values of t_{χ_R} , from 10^{-1} to infinity.

45 GeV. Even if we allow the bulk mass M to be nonzero, we cannot do much better, since Eq. (4.15) involves M in a dramatic way. In particular, when $M \rightarrow -\infty$, t_L tends exponentially to zero, and so does m_0 . In the other limit of $M \rightarrow \infty$, the solution for m_0 itself is exponentially suppressed, as shown in Eq. (3.19). Thus we find a peak near $M = 0$ in the curve for m_0 as a function of M (for fixed t_{χ_R}), as shown in Fig. 2. From this curve with $1/R = 500$ GeV, we find that the maximum possible quark mass for any value of M is about 47 GeV, which occurs for t_{χ_R} set to infinity.

One possible way to solve this problem is to allow a different t_L for the third generation of quarks. This approach might be viable, since the constraints on the S parameter do not directly involve the third generation fermions. However, we find it unattractive, since universality of t_L (and M) was the simplest way to avoid any dangerous flavor-changing neutral currents. An alternate solution that we prefer is to allow a different size of R for the gauge sector and the fermion sector. This possibility had been suggested in the context of the warped-space model in Ref. [26]. It is even more sensible in the context of a theory space, since there is no reason for the coefficients of $\bar{\psi}\Gamma^\mu D_\mu\psi$ and $\bar{\psi}\Gamma^5 D_5\psi$ to be

identical, in the bulk sector of Eq. (3.1). In terms of the deconstructed [33, 34] version of the theory, this just corresponds to allowing the gauge couplings and the Yukawa couplings to be independent of each other [35]. The most general extension of model II, with y -independent parameters, is described by the action $\mathcal{S} + \mathcal{S}^{(II) \prime}$, where $\mathcal{S}$ is just the gauge sector action given in Eq. (2.1), and

$$\begin{aligned} \mathcal{S}^{(II) \prime} = \int_0^{\pi R} dy \int d^4x \left[\frac{1}{\pi R} \left(\bar{\psi} i \Gamma^\mu D_\mu \psi + \kappa \left(\frac{1}{2} \bar{\psi} i \Gamma^5 D_5 \psi + \text{h.c.} \right) - M \bar{\psi} \psi \right) \right. \\ \left. + \delta(y) \frac{1}{t_L^2} i \bar{\psi}_L \not{D} \psi_L + \delta(\pi R - y) \left(\frac{1}{t_{u_R}^2} i \bar{u}_R \not{D} u_R + \frac{1}{t_{d_R}^2} i \bar{d}_R \not{D} d_R \right) \right], \end{aligned} \quad (5.1)$$

where κ is a new parameter.[†] Rescaling the parameter y by $y \rightarrow y' = y/\kappa$, the action $\mathcal{S}^{(II) \prime}$ becomes identical to $\mathcal{S}^{(II)}$, with R replaced by R/κ .[‡] Therefore, the gauge sector mass scale, $1/R_g \equiv 1/R$, and the fermion sector mass scale, $1/R_f \equiv \kappa/R$, are independent quantities in theory space: setting $R_f = R_g$ is an unnecessary and arbitrary choice.

With the action $\mathcal{S}^{(II) \prime}$ replacing $\mathcal{S}^{(II)}$, the fermion masses are (for $M = 0$),

$$\hat{m}_0 = \kappa \frac{t_L t_{\chi_R}}{\sqrt{1 + t_{\chi_R}^2}} \left[1 - \frac{1 + t_{\chi_R}^2 + t_{\chi_R}^4/3}{2(1 + t_{\chi_R}^2)^2} t_L^2 + \mathcal{O}(t_L^4) \right] \quad (5.2)$$

$$\hat{m}_n = \kappa \pi \left(n - \frac{1}{2} \right) \left[1 + \frac{t_L^2 + t_{\chi_R}^2}{\pi^2 (n - \frac{1}{2})^2} + \mathcal{O}(t^4) \right]; \quad n = 1, 2, \dots \quad (5.3)$$

Now we can account for m_t by simply increasing κ . Furthermore, it is now possible to suppress the right-handed couplings in Eq. (4.17), since a larger κ requires a smaller t_{χ_R} to obtain a given fermion mass. Of course κ (and $1/R_f$) cannot be too large, due to unitarity constraints similar to those which give bounds on $1/R_g$. In the case of $1/R_f$ the limits come from scattering processes such as $t\bar{t} \rightarrow W_L^+ W_L^-$. We shall investigate these unitarity bounds in the next section.

6. Unitarity Constraints

Here we shall restrict ourselves to considering the unitarity bounds coming from the $t\bar{t} \rightarrow W_L^+ W_L^-$ scattering process. General constraints on couplings in Higgsless models from this and related processes have been considered previously in Ref. [39]. In the SM, the tree-level $t\bar{t} \rightarrow W_L^+ W_L^-$ scattering amplitude is given by the four diagrams of Fig. 3(a). If t and $\bar{t}$ have opposite helicities, the γ - and Z -exchange diagrams produce quadratically divergent terms, in the high-energy limit, which are cancelled by the b -exchange diagram [1]. The Higgs boson is not involved in this cancellation, which is confined to the $J = 1$ partial wave, so there is no quadratic growth of the amplitude with energy, regardless of the Higgs

[†]From an extra-dimensional point of view, this action corresponds to a theory with a microscopic breaking of the five-dimensional Lorentz invariance, in addition to the macroscopic breaking due to the compactification.

[‡]The only difference is the interaction term with W_5^a , which is zero in unitary gauge anyway.

Figure 3: (a) Diagrams contributing to the $t\bar{t} \rightarrow W_L^+ W_L^-$ tree-level scattering amplitude in the SM. (b) Same process, in theory space.

boson mass. If t and $\bar{t}$ have the same helicity, the b -exchange diagram produces a linearly divergent high-energy term in the $J = 0$ channel, which is cancelled by the Higgs boson exchange diagram.

In our Higgsless model the Higgs boson exchange diagram, of course, does not occur. The γ -, Z -, and b -exchange diagrams are supplemented by corresponding diagrams with exchange of heavy Z_n 's and b_n 's, as shown in Fig. 3(b). As $1/R_f \rightarrow \infty$, these heavy Z_n 's and b_n 's are removed from the theory, and it becomes equivalent to the SM without the Higgs boson. Thus, it is reasonable to expect that the cancellation that occurs for opposite helicity t and $\bar{t}$ in the SM also occurs in our Higgsless model, and that the amplitude does not display quadratic energy growth at any scale. We have directly verified this in our model. However, if the t and $\bar{t}$ have the same helicity, the linear growth in energy, that was cancelled by Higgs boson exchange in the SM, now must be cancelled by some other sector of the theory. In our Higgsless model this cancellation occurs through the b_n -exchange diagrams. In this respect, the heavy b -quarks play the role of the SM Higgs boson for this scattering process.

In Ref. [17] we used the quadratic growth in energy of the $W_L^+ W_L^- \rightarrow W_L^+ W_L^-$ scattering amplitude to place approximate bounds on the scale $1/R_g$, where the heavy vector states come in to restore unitarity. We can now do the same here, using the $t\bar{t} \rightarrow W_L^+ W_L^-$ process to place approximate bounds on $1/R_f$. Note that, since the fermion amplitude

only shows linear growth with energy in the high-energy limit, the corresponding limits on the heavy fermion states will be significantly weaker.

For left-handed t and $\bar{t}$, the $J = 0$ partial wave amplitude is given by

$$a_0(t_L \bar{t}_L \rightarrow W_L^+ W_L^-) = \frac{1}{64\pi} \sum_{n=0}^{\infty} \frac{1}{p^2 + k^2 + m_{b_n}^2} \left[((h_{Ln}^{CC})^2 + (h_{Rn}^{CC})^2) \left(m_t k g(\xi_n) + 2 \frac{m_t}{m_W^2} p E^2 h(\xi_n) - m_t p f(\xi_n) \right) + \frac{m_{b_n}}{m_W^2} h_{Ln}^{CC} h_{Rn}^{CC} (4k E^2 g(\xi_n) - 2p(2E^2 - m_W^2) f(\xi_n)) \right], \quad (6.1)$$

where

$$\xi_n \equiv \frac{2pk}{p^2 + k^2 + m_{b_n}^2}, \quad (6.2)$$

E and p are the t (or $\bar{t}$) energy and momentum, respectively, k is the W_L^+ (or W_L^-) momentum, and m_{b_n} is the b_n mass, with $m_{b_0} \equiv m_b$. The functions $f(x)$, $g(x)$, and $h(x)$ are

$$\begin{aligned} f(x) &= \frac{1}{x} \ln \frac{1+x}{1-x} \\ g(x) &= -\frac{2}{x} \left(1 - \frac{1}{2x} \ln \frac{1+x}{1-x} \right) \\ h(x) &= \frac{2}{x^2} \left(1 - \frac{1-x^2}{2x} \ln \frac{1+x}{1-x} \right). \end{aligned} \quad (6.3)$$

The couplings h_{Ln}^{CC} and h_{Rn}^{CC} are obtained from the generalizations of Eqs. (4.9) and (4.16) by replacing $u \rightarrow t$, $d \rightarrow b_n$, and $W_n \rightarrow W_0 \equiv W$; that is[§],

$$\begin{aligned} h_{Ln}^{CC} &= \int_0^{\pi R} dy \left[\frac{1}{\pi R} + \frac{1}{t_L^2} \delta(y) \right] f_0(y) \alpha_{t_0}(y) \alpha_{b_n}(y) \\ h_{Rn}^{CC} &= \int_0^{\pi R} dy \frac{1}{\pi R} f_0(y) \beta_{t_0}(y) \beta_{b_n}(y) \end{aligned} \quad (6.4)$$

For $M = 0$, to leading order in t_L^2 , $t_{b_R}^2$, and λ^2 , they are

$$\begin{aligned} h_{L0}^{CC} &= g [1 + \mathcal{O}(t^2)] \\ h_{Ln}^{CC} &= g \frac{\sqrt{2} t_L}{1 + t_{t_R}^2} \left[\frac{(-1)^{n+1}}{\pi^2 (n - \frac{1}{2})^2} + \frac{2 t_{t_R}^2}{\pi^3 (n - \frac{1}{2})^3} \right] [1 + \mathcal{O}(t^2)]; \quad n = 1, 2, \dots \\ h_{R0}^{CC} &= g \frac{t_{t_R} t_{b_R}}{2 \sqrt{1 + t_{t_R}^2}} [1 + \mathcal{O}(t^2)] \\ h_{Rn}^{CC} &= g \frac{\sqrt{2}}{\pi^2 (n - \frac{1}{2})^2} \frac{t_{t_R}}{\sqrt{1 + t_{t_R}^2}} [1 + \mathcal{O}(t^2)]; \quad n = 1, 2, \dots \end{aligned} \quad (6.5)$$

Figure 4: Bounds imposed by unitarity constraints on the $t\bar{t} \rightarrow W_L^+ W_L^-$ scattering at $\sqrt{s}=10$ TeV (upper curve), and the $W_L^+ W_L^- \rightarrow W_L^+ W_L^-$ scattering at $\sqrt{s}=10$ TeV and $\sqrt{s}=5$ TeV (vertical lines), in the $(1/R_g, 1/R_f)$ plane. Specifically, we have assumed the requirement of $a_0 < 1/2$ for both scattering processes. The $t\bar{t} \rightarrow W_L^+ W_L^-$ scattering at $\sqrt{s}=5$ TeV imposes no bound, since at this energy even the SM without Higgs boson does not violate unitarity. The two curves on the bottom correspond to the minimum value of $1/R_f$ which allows a top mass of 175 GeV to be a solution of the mass equation for $M = 0$ (lower), and the minimum value of $1/R_f$ which gives a tbW right-handed coupling in agreement with the experimental constraint (upper).

In the high energy limit, Eq. (6.1) becomes

$$a_0(t_L \bar{t}_L \rightarrow W_L^+ W_L^-) \simeq \frac{1}{32\pi} \frac{m_t E}{m_W^2} \sum_{n=0}^{\infty} \left((h_{Ln}^{CC})^2 + (h_{Rn}^{CC})^2 - 2 \frac{m_{b_n}}{m_t} h_{Ln}^{CC} h_{Rn}^{CC} \right). \quad (6.6)$$

It is straightforward to show that this vanishes, to leading order in t_L^2 , $t_{b_R}^2$, and λ^2 , using the couplings given in Eq. (6.5) and the masses given in Eq. (5.2) and Eq. (5.3), applied to m_t and m_{b_n} , respectively. In fact, using the completeness relations

$$\sum_{n=0}^{\infty} \left(\frac{1}{\pi R} + \frac{\delta(y)}{t_L^2} \right) \alpha_{b_n}(y) \alpha_{b_n}(y') = \delta(y - y')$$

[§]In this section we have omitted the superscript “(II)” on the gauge couplings.

Figure 5: Right-handed tbW coupling, in units of e/s , for $1/R_g = 550$ GeV, as a function of $1/R_f$. The horizontal line corresponds to the experimental bound of Ref. [40].

$$\sum_{n=0}^{\infty} \left(\frac{1}{\pi R} + \frac{\delta(y)}{t_{b_R}^2} \right) \beta_{b_n}(y) \beta_{b_n}(y') = \delta(y - y'), \quad (6.7)$$

as well as the equations of motion, Eq. (3.8), and the boundary conditions, Eq. (3.9), for the t , and the b_n 's, it can be shown that

$$\sum_{n=0}^{\infty} \left((h_{Ln}^{CC})^2 + (h_{Rn}^{CC})^2 - 2 \frac{m_{b_n}}{m_t} h_{Ln}^{CC} h_{Rn}^{CC} \right) \equiv 0. \quad (6.8)$$

Therefore, this cancellation is exact in this model for any values of the couplings, and the linear growth in energy at high energies does not occur.

Of course, the cancellation of the term that grows with energy is not a sufficient condition for the unitarization of the amplitude: the latter could stop growing after unitarity is already violated. The heavy b -quarks should come into play early enough to cancel the bad high-energy behavior, and this is only possible if $1/R_f$ is not too large. Enforcing Eq. (4.15), to keep S fixed at zero, and setting $M = 0$, the only parameters that are not fixed by the light SM fermions and bosons are R_g and R_f , which set the scale for the heavy vector

bosons and the heavy fermions, respectively. We can put some reasonable constraints on these two parameters by requiring that the $t_L \bar{t}_L \rightarrow W_L^+ W_L^-$ and the $W_L^+ W_L^- \rightarrow W_L^+ W_L^-$ scattering amplitudes remain unitary up to some value of the center-of-mass energy $\sqrt{s}$. As an example, in Fig. 4 we display the region in the $(1/R_g, 1/R_f)$ plane that is allowed by the requirement that $a_0 < 1/2$ up to $\sqrt{s} = 10$ TeV or $\sqrt{s} = 5$ TeV for both scattering amplitudes[¶]. As expected, we see that $1/R_f$ can indeed be much larger than $1/R_g$. If we require the theory to respect unitarity up to $\sqrt{s} = 10$ TeV in both amplitudes, we find $1/R_g \lesssim 570$ GeV and $1/R_f \lesssim 32$ TeV. If we use the weaker requirement that the theory only respect unitarity up to $\sqrt{s} = 5$ TeV, then we find $1/R_g \lesssim 720$ GeV, while there is no constraint on $1/R_f$, since the $t_L \bar{t}_L \rightarrow W_L^+ W_L^-$ scattering amplitude does not violate unitarity at this energy even in the SM without a Higgs boson. Of course, any bounds on $1/R_g$ and $1/R_f$ depend on the somewhat arbitrary scale choice for $\sqrt{s}$, where the low energy Higgsless theory has broken down.

Lower limits on the scales $1/R_g$ and $1/R_f$ can be obtained from experimental input. In Ref. [17] it was estimated that $1/R_g \gtrsim 500$ GeV from limits on W' and Z' states with appropriate couplings. This lower limit should be even weaker in model II, with delocalized fermions, since the coupling between the light fermions and the heavy vector states have an additional, order one, suppression relative to that in model I, as given in Eqs. (4.10). For the case of $1/R_f$, a minimal requirement is that it be large enough to accommodate a top quark mass of 175 GeV. This is displayed in the lower curve on the bottom of Fig. 4. It gives a lower bound of $1/R_f \gtrsim 1 - 3$ TeV, with the dependence on $1/R_g$ entering through the condition imposed by Eq. (4.15). However, this curve corresponds to an infinite value of t_{t_R} , which is not viable. Tighter constraints can be obtained by limits on the right-handed tbW and ttZ couplings, which are evaluated to lowest order in t_{χ_R} in Eqs. (4.17). For example, in Ref. [40] it is estimated, using experimental results on the $b \rightarrow s\gamma$ process, that $g_R^{CC}(t, b, W^\pm)/g \leq 0.4 \cdot 10^{-2}$, at the 2σ level. The corresponding bound on $1/R_f$ is displayed in the upper curve on the bottom of Fig. 4. For the particular value of $1/R_g = 550$ GeV, we can see how the coupling $g_R^{CC}(t, b, W^\pm)/g$ (where we have used $g \equiv e/s$) varies with $1/R_f$ in Fig. 5. The experimental bound is satisfied for this value of $1/R_g$ by $1/R_f \gtrsim 3.6$ TeV, which corresponds to $\kappa \gtrsim 6.5$. An even stronger bound might be obtainable from limits on the right-handed neutral current coupling, since it is quadratic in the parameter t_{t_R} ; however, the extraction of this coupling requires more detailed analysis of higher order effects at the Z -pole in our model.

7. Conclusions

In this paper we have completed the construction of a phenomenologically viable higgsless model from theory space, by extending and generalizing the models of Refs. [17] and [27]. This model contains three features, which are crucial to any viable higgsless model of electroweak symmetry breaking. First, it contains a tower of vector bosons which delay the unitarity violation in the $W_L W_L \rightarrow W_L W_L$ and $W_L Z_L \rightarrow W_L Z_L$ scattering amplitudes,

[¶]The expression for the $W_L^+ W_L^- \rightarrow W_L^+ W_L^-$ scattering amplitude can be obtained by taking the $N \rightarrow \infty$ limit of Eq. (3.7) in Ref. [17].

while giving the correct mass for the standard model $W^\pm$ and Z (and photon) as the lightest states in the tower. Thus, it can extend the applicability of the effective higgsless theory up to a higher scale in the 5-10 TeV range. This is accomplished using an $SU(2)$ gauge symmetry on a theory-space interval, broken down to $U(1)$ at the right end of the interval, and with gauge kinetic terms on each end of the interval. The normalization (λ, λ') of the gauge kinetic terms on the boundaries are easily arranged to give the correct mass for the SM $W^\pm$ and Z bosons.

Second, it incorporates a cancellation of the large vector boson contributions to the S parameter, which generically occur in higgsless models. This cancellation is obtained by allowing the light fermion wave functions to leak away from the ends of the interval. In our model this leakage arises through boundary conditions and boundary kinetic terms for the fermions, where the light left-handed fields are predominantly located at the left end of the interval and the right-handed fields are predominantly located at the right end of the interval. The leakage of the left-handed fields into the bulk can be made to cancel the gauge boson contributions to S , while keeping the T and U parameters naturally suppressed, by tuning the normalization (t_L) of the universal left-handed fermion kinetic term on the left boundary. Meanwhile the normalization (t_{χ_R}) of the right-handed fermion kinetic terms on the right boundary can be used to give the correct mass for each of the light fermions. Furthermore, multiple generations and fermion mixings are implemented in the model, without introducing flavor-changing neutral currents, by confining all flavor physics to the right-handed fermion brane kinetic terms, and imposing a global $U(3)_{quark} \times U(3)_{lepton}$ symmetry on the bulk and left brane.

Third, it has a realistic top quark mass and small nonstandard right-handed top and bottom couplings. To obtain this goal, while maintaining the good unitarity properties of the $W_L W_L$ scattering, it was necessary to separate the overall gauge sector scale $(1/R_g)$ from the overall fermion sector scale $(1/R_f)$. This requires an explicit breaking of the five-dimensional Lorentz symmetry, which is theoretically allowed, since such symmetry is already broken by compactification and brane kinetic terms. In fact, within a theory-space model it can be considered natural, since the difference in the size of the scales is analogous to having different sizes of gauge and Yukawa couplings. By making $1/R_f$ larger than $1/R_g$, it is possible to obtain the top quark mass. It is also possible to suppress any nonstandard right-handed top and bottom couplings, since for a fixed fermion mass, an increase in $1/R_f$ requires a compensatory decrease in t_{χ_R} , leading to a decrease in right-handed couplings.

In this way, we have constructed a viable higgsless model with only three undetermined parameters, $1/R_g$, $1/R_f$, and the bulk fermion mass M . Since the bulk fermion mass does not seem to add any qualitatively new features to the model, it is reasonable to set $M = 0$, leaving us with a two-parameter model. The parameter $1/R_g$ sets the scale of the vector boson excitations, and the parameter $1/R_f$ sets the scale of the fermionic excitations. Just as the scale $1/R_g$ cannot be too large and still effectively delay unitarity violation in $W_L W_L \rightarrow W_L W_L$ scattering, the scale $1/R_f$ cannot be too large and still effectively delay unitarity violation in $t\bar{t} \rightarrow W_L W_L$ scattering. Thus, both of these scales are bounded from above, the exact bounds depending on the energy scale at which the effective higgsless theory must be replaced by a more complete theory. A reasonable upper bound for $1/R_g$ is

in the 570-720 GeV range, while the upper bound for $1/R_f$ is much weaker, of order 30 TeV or more. Experimental lower limits on $1/R_f$ from right-handed tbW couplings are in the range of 2-4 TeV. Precise experimental lower limits on $1/R_g$ require further investigation, although given the small couplings between the light fermions and the heavy W' and Z' states, there appears to be a reasonable range for this parameter that is still allowed.

In conclusion, we have presented an existence proof of a viable higgsless model, that can satisfy all current experimental constraints, as far as we know. It is certainly not the only higgsless model that may work, and it is probably too simplistic in many regards, but it has all of the features that any higgsless model must have. Thus, it offers a concrete example for use to explore the phenomenology of higgsless models at the Tevatron and the LHC. In particular, it is worthwhile to further investigate its most relevant phenomenological aspects, with careful attention to those features which are general, rather than characteristic of any particular model.
